A novel Gram-stain-negative, rod shaped, motile bacterium, designated strain AK21^T, was isolated from coastal sea surface water, Visakhapatnam, India. The strain was positive for oxidase, catalase, lipase, L-proline arylamidase and tyrosine arylamidase activities. The predominant fatty acids were C_{12:0}, C_{12:0} 3OH, C_{16:0}, C_{16:1} \omega 9c, C_{18:1} \omega 9c and C_{16:1} \omega 7c and/or iso-C_{15:0} 2-OH (summed feature 3). The polar lipids were diphosphatidylglycerol (DPG), phosphatidylethanolamine (PE), phosphatidylglycerol (PG), one unidentified aminophospholipids (APL), two unidentified phospholipids (PL) and one unidentified lipid (L). Q-10 is the predominant respiratory quinone. The DNA G + C content of the strain was 54.6 mol%. The 16S rRNA gene sequence analysis indicated that strain AK21^T was member of the genus Marinobacter and closely related to Marinobacter xestospongiae with pair-wise sequence similarity of 97.2% and with other members of the genus is between 94.0 to 96.8%. The average DNA-DNA relatedness of the strain AK21^T with M. xestospongiae JCM 17469^T was 34.5% and with M. mobilis JCM 15154^T was 40.5%. Phylogenetic analysis showed that strain AK21^T clustered with Marinobacter xestospongiae and Marinobacter mobilis with a distance of 2.9 and 2.8% (97.1 and 97.2% similarity), respectively. Based on the phenotypic characteristics and on phylogenetic inference, it appears that strain AK21^T represents a novel species of the genus Marinobacter, for which the name Marinobacter nitratireducens sp. nov. is proposed. The type strain of Marinobacter nitratireducens sp. nov. is AK21^T (MTCC 11704^T = JCM 18428^T).
The genus *Marinobacter*, proposed by Gauthier et al. (1992) with the type species *Marinobacter hydrocarbonoclasticus*, isolated from sediment of the Gulf of Fos (French Mediterranean coast), belongs to the family *Alteromonadaceae* in the class *Gammaproteobacteria*. The genus currently comprises 36 species with validly published names, including the recently described *Marinobacter persicus* (Bagheri et al., 2013), *M. adhaerens* (Kaeppel et al., 2012), *M. antarcticus* (Liu et al., 2012), *M. xestospongiae* (Lee et al., 2012), *M. zhanjiangensis* (Zhuang et al. 2009), *M. daqiaonensis* (Qu et al., 2011), *M. oulmenensis* (Kharroub et al., 2011) and two validated species *M. salarius* and *M. similis* (Oren and Garrity, 2015). Members of the genus *Marinobacter* were isolated from diverse habitats like marine aggregates formed with the diatom *Thalassiosira weissflogii* (Kaeppel et al., 2012), paralytic shellfish toxin-producing dinoflagellates (Green et al., 2006), Antarctic marine habitats (Liu et al., 2012; Montes et al., 2008; Shivaji et al., 2005), Vietnamese oil-producing well (Nguyen et al. 1999), marine Bryozoa specimen (Romanenko et al., 2005), marine sediments (Gorshkova et al., 2003; Guo et al., 2007; Huo et al., 2008; Romanenko et al., 2005), sea water (Gauthier et al., 1992; Roh et al., 2008; Xu et al., 2008; Yoon et al., 2003, 2004; Zhuang et al., 2009), salt pond (Qu et al., 2011), oil-polluted saline soil (Gu et al., 2007), sea sand (Kim et al., 2006), hypersaline lake water (Aguilera et al., 2009; Bagheri et al., 2013), saline soil (Martin et al., 2005), coastal hot spring (Shieh et al., 2003), brine-seawater (Antunes et al., 2007), brine of a salt concentrator (Kharroub et al., 2011), marine solar salters (Wang et al., 2009; Yoon et al., 2007), sea-ice of Arctic (Zhang et al., 2008), hydrothermal sediment (Handley et al., 2009), wine-barrel-decalcification wastewater (Liebgott et al., 2006) and marine sponge *Xestospongia testudinaria* (Lee et al., 2012). *Marinobacter aquaeolei* is a later heterotypic synonym of *Marinobacter hydrocarbonoclasticus* (Márquez and Ventosa 2005). In the present study we focused on the characterization and classification of a strain AK21T, which was isolated from marine water sample, by polyphasic taxonomic approaches (Vandamme et al. 1996) and proposing new species of the genus *Marinobacter* for which the name *M. nitratireducens* sp. nov. is proposed.

Strain AK21T was isolated from a coastal sea surface water sample collected from sea shore, Rushikonda beach (GPS positioning 17°46′54.08″N 83°23′10.29″E), Bay of Bengal, Visakhapatnam, India. The sample (1 ml) was serially diluted (10 fold dilutions) and 100 μl of each dilution was plated on marine agar medium and incubated at 30 °C. A shiny cream colored colony was observed upon five days incubation, which was purified and preserved as -70 °C glycerol stock for further characterization.

Type strains for comparative characterization were procured from Japan Collection of Microorganisms, Japan (*Marinobacter mobilis* JCM 15154T, *Marinobacter xestospongiae* JCM
Strain AK21T was characterized simultaneously with *M. mobilis* JCM 15154T, *M. xestospongiae* JCM 17469T and *M. hydrocarbonoclasticus* DSM 8798T. Cell morphology studies of the strain AK21T were done by phase contrast microscopy (Olympus). Physiological properties such as growth at different temperatures 5, 10, 15, 20, 25, 28, 30, 33, 35, 37, 40, 42 and 45 °C was tested by growing on Marine broth, and at different NaCl concentrations (0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13 and 14% w/v) was tested by growing on Nutrient broth (Lányi, 1987). Growth of strain AK21T at pH 5, 6, 6.5, 7, 7.5, 8, 8.5, 9, 10 and 11 was assessed on Marine broth buffered with citric acid/NaOH (for pH 5 and 6), NaHPO₄/Na₂HPO₄ (for pH 6.5, 7 and 8), glycine/NaOH (for pH 8.5, 9 and 10), Na₂HPO₄/NaOH (for pH 11). Different biochemical tests listed in description of species and as well as in Table 1 were carried out using the culture that was grown at 30 °C on MA medium as described by Lányi (1987) (catalase, oxidase activities, nitrate reduction, indole production and aesculin hydrolysis) and Smibert & Krieg (1994) (H₂S production, gelatin and urea hydrolysis). Extracellular enzymatic activities like amylase, lipase and protease, were studied as described by Srinivas et al. (2009). Biochemical and enzymatic characterizations, carbon substrate utilization, acid production and antibiotic susceptibility of the strains were performed using previously described methods (Anil Kumar et al., 2012).

Standardization of the physiological age of strains AK21T, *M. mobilis* JCM 15154T and *M. xestospongiae* JCM 17469T was done based on the protocol (http://www.microbialid.com/PDF/TechNote_101.pdf) given by Sherlock Microbial Identification System (MIDI, USA). For cellular fatty acids analysis, strains AK21T, *M. mobilis* JCM 15154T and *M. xestospongiae* JCM 17469T were grown on MA plates at 30 °C for 2-3 days (all three stains are at same phase of their growth). Cellular fatty acid methyl esters (FAMEs) were obtained from cells by saponification, methylation and extraction following the protocol of MIDI. Cellular FAMEs were separated by GC (6890) and identified and quantified using the Sherlock Microbial Identification System (MIDI-6890 with database TSBA6). Freeze-dried cells following growth were analysed from polar lipids and quinones. Isoprenoid quinones were extracted as described by Collins *et al.* (1977) and analysed by HPLC (Groth *et al*., 1997). Cells of strain AK21T and other three type strains were extracted for the polar lipid analysis (Bligh & Dyer, 1959) and analyzed by 2D thin-layer chromatography followed by spraying with appropriate detection reagents (5% ethanolic molybdatophosphoric acid, molybdenum blue, ninhydrin and molisch reagents) (Komagata & Suzuki, 1987). Genomic DNA was isolated by using the procedure of Marmur (1961) and the mol%
G + C content was determined from melting point ($T_m$) curves (Sly et al., 1986) obtained by using Lambda 35; Perkin Elmer spectrophotometer equipped with Templab 2.0 software package.

For 16S rRNA gene sequencing, DNA was prepared using a bacterial DNA isolation kit (Qiagen). The 16S rRNA gene was amplified by PCR using universal bacterial primers 27f (5'-AGAGTTTGATCCTGGCTCAG-3') and 1492r (5'-TACGGYTACCTTGTTACGACTT -3'). The PCR product was purified using QIA quick PCR purification kit (Qiagen) and it was sequenced using an ABI PRISM model 3700 automatic DNA sequencer and Big Dye Terminator cycle sequencing kit (Applied Biosystems). The 16S rRNA gene sequence of strain AK21$^T$ was subjected to BLAST sequence similarity search (Altschul et al., 1990) and EzBioCloud (Kim et al., 2012) to identify the nearest taxa. Based on BLAST results, all 16S rRNA gene sequences of the genus Marinobacter were downloaded from the NCBI database (http://www.ncbi.nlm.nih.gov) and aligned using the CLUSTAL_W program in MEGA5 (Tamura et al., 2011). The evolutionary history was inferred by using the maximum-likelihood method (Tamura & Nei, 1993), neighbor-joining (NJ) method (Saitou & Nei, 1987) and maximum-parsimony method (Nei & Kumar, 2000) using the MEGA5 package (Tamura et al., 2011). The tree is drawn to scale, with branch lengths measured in the number of substitutions per site. All positions containing gaps and missing data were eliminated. There were a total of 1355 positions in the final dataset. Evolutionary analyses were conducted in MEGA5 (Tamura et al., 2011). The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test (1,000 replicates) is shown next to the branches (Felsenstein, 1985). DNA-DNA hybridization was performed by the membrane filter method (Tourova and Antonov, 1987) as described previously (Rakshak et al., 2013).

Cells of the strain AK21$^T$ were Gram-stain-negative, rod shaped, 0.8-1.0 µm wide x 2.0-3.0 µm long, multiply by binary fission and motile by single polar flagellum (Fig. 2). Chain formation is seen when grown on MA for 2-3 days at 30 °C. Colonies were circular, 2-3 mm in diameter, smooth, slimy, shiny, opaque, creamish and raised with entire margin on MA plates grown at 30 °C for two days. Grows chemoorganoheterotrophically. The strain grew between 15 to 42 °C temperature and optimum being 28 to 35 °C, from pH 6 to 10, with the optimum growth at pH 7 and from salinity 0.5 to 6% (NaCl, w/v), with optimum growth occurred at salinity 2% (NaCl, w/v). Other phenotypic characteristics of the strain AK21$^T$ are listed in the species description and in Tables 1 and 2.

The fatty acid profile was dominated by saturated and unsaturated straight chain and hydroxy fatty acids, like C12:0 (9.5%), C12:0 3OH (10.6%), C16:1 ω9c (20.4%), C16:0 (24.7%), C18:1 ω9c (19.9%) and C16:1 ω7c and/or iso-C15:0 2-OH (summed feature 3) (5.3%) (Table 2). Over all fatty acid composition of strain AK21$^T$ was similar to those of the two reference strains and however, the isolate AK21$^T$
could be clearly distinguished from the reference strains by the absence or low or high amount of C$_{18:1}$ $\omega7c$, summed feature 3, C$_{18:1}$ $\omega9c$ and C$_{16:1}$ $\omega9c$ (Table 2). The low and high amounts of fatty acids summed feature 3, C$_{18:1}$ $\omega9c$ and C$_{16:1}$ $\omega9c$ were comparable with *M. hydrocarbonoclasticus* DSM 8798$^T$ (Table 2). Strain AK21$^T$ contained diphosphatidylglycerol (DPG), phosphatidylethanolamine (PE), phosphatidylglycerol (PG), one unidentified aminophospholipid (APL), two unidentified phospholipids (PL) and one unidentified lipid (L) as total polar lipids (Fig. S1a). In type strains also nearly similar composition (DPG, PE, PG and APL) was observed but differed with strain AK21$^T$ either in the absence or the presence of of PL1-PL4 and L1-L7 (Fig. S1 b, c and d). Q-10 is the predominant respiratory quinone. The other type strains also comprise Q-10 as predominant respiratory quinone. DNA G + C content of the strain AK21$^T$ was 54.6 mol% (Tm) (Table 1) which is different from the compared strains but within the genus.

Phylogenetic relationships of strain AK21$^T$ based on the 16S rRNA gene sequence indicated that strain AK21$^T$ was close to the *M. xestospongiae* with pair-wise sequence similarity of 97.2%. With the other members of the genus *Marinobacter* the strain AK21$^T$ showed 94.0 to 96.8% pair-wise sequence similarity. The phylogenetic tree obtained using the neighbor-joining (Fig. 1) method revealed clustering of strain AK21$^T$ with *M. xestospongiae*, *M. zhejiangensis* and *M. mobilis* with a distance of 2.9, 3.9 and 2.8% (97.1, 96.1 and 97.2% similarity), respectively. The other phylogenetic trees obtained using the maximum-likelihood (Supplementary Fig. S2) and maximum parsimony (Supplementary Fig. S3) methods revealed similar topology at this cluster. Based on the 16S rRNA gene sequence analysis strain AK21$^T$ was falling within the cut off limit <97% similarity with two strains *M. xestospongiae* and *M. mobilis* and was above the cut off limit with *M. zhejiangensis* (96.1% similarity). DNA–DNA hybridization experiment was preformed between the strain AK21$^T$ and the type strains of two closely related phylogenetic neighbours, *M. xestospongiae* JCM 17469$^T$ and *M. mobilis* JCM 15154$^T$. The average relatedness of the strain AK21$^T$ with *M. xestospongiae* JCM 17469$^T$ was 34.5% and with *M. mobilis* JCM 15154$^T$ was 40.5%.

The main features of the strain AK21$^T$ are in line with the original description of the genus *Marinobacter* but could be distinguished from published closely related species *M. xestospongiae*, *M. mobilis* and type species of the genus *M. hydrocarbonoclasticus* (Tables 1 and 2). Thus, the cumulative differences of strain AK21$^T$ from the closely related type strains unambiguously classify the strain as a new species of the genus *Marinobacter* for which the name *Marinobacter nitratireducens* sp. nov. is proposed.

**Description of *Marinobacter nitratireducens* sp. nov.**
Marinobacter nitratireducens (ni.tra.ti.re.du’cens. N.L. n. nitras -atis nitrate; L. part. adj. reducens converting to a different state; N.L. adj. nitratireducens reducing nitrate).

Cells are Gram-stain-negative, rod shaped, 0.8-1.0 µm wide x 2.0-3.0 µm long and motile by single polar flagellum. Cells form chains, multiply by binary fission and are motile. Colonies grown for 2 days at 30 °C on MA plates are circular, 2-3 mm in diameter, smooth, slimy, shiny, opaque, cream and raised with entire margin. Grows at 15-42 °C (optimum, 28-35 °C), and at pH 6-10 (optimum, 7.0). Optimum growth occurred at salinity 2% (w/v) and tolerates up to 6% (w/v). Cells require NaCl for growth. Positive for catalase, oxidase and arginine dihydrolase activities. Methyl red and Voges Proskauer’s reactions are negative. Nitrate is reduced but H₂S and indole are not produced. Hydrolyzed Tween 20/40/60/80 but not agar, aesculin, casein, gelatin, starch and urea. Produces acid from fructose, dextrose, sucrose, inulin, sodium gluconate, glycerol, inositol, sorbitol, mannitol, arabinol and α-methyl-D-glucoside in the Hi25™ Enterobacteriaceae Identification Kit, and is able to ferment the same sugars, using the HiCarbohydrate™ Kit and produce acid weakly from rhamnose but not from lactose, xylose, maltose, galactose, raffinose, trehalose, melibiose, D-arabinose, L-arabinose, mannose, salicin, dulcitol, adonitol, erythritol, cellobiose, melezitose, α-methyl-D-mannoside, xylitol, citrate, malonate and sorbose. Positive reactions (from VITEK 2 GN) in tests for L-proline arylamidase, lipase and tyrosine arylamidase; negative reactions were observed for Ala-Phe-Pro-arylamidase, L-pyrrolydonyl-arylamidase, β-galactosidase, β-N-acetylglucosaminidase, glutamyl arylamidase, γ-glutamyl-transferase, β-glucosidase, β-xylosidase, β-alanine arylamidase, α-glucosidase, β-N-acetylgalactosaminidase, α-galactosidase, phosphatase, glycine arylamidase, lysine decarboxylase, ornithine decarboxylase, β-glucoronidase and glu-gly-arg-arylaminidase, adonitol, L-arabitol, D-cellobiose, D-glucose, D-maltose, D-mannitol, D-mannose, palatinose, D-sorbitol, sucrose, D-tagatose, D-trehalose, citrate, malonate, 5-keto-D-gluconate, L-histidine, L-lactate, L-malate, fermentation of glucose, L-lactate and succinate alkalisation, curmarate, ELLMAN and 0/129 resistance. Susceptible to antibiotics, gentamycin, chloramphenicol, amoxicillin and ampicillin; moderately resistant to N, ceftazidime and erythromycin; resistant to kanamycin, tetracycline, lincomycin, vancomycin, chlorotetracycline, cephaloxil, novobiocin, enoxacin and methicillin. The predominant fatty acids were C₁₂:0, C₁₂:0 3OH, C₁₆:₁ ω₉c, C₁₆:₀, C₁₈:₁ ω₉c and C₁₆:₁ ω₇c and/or iso-C₁₅:₀ 2-OH (summed feature 3). The polar lipids consisted of diphosphatidylglycerol (DPG), phosphatidylethanolamine (PE), phosphatidylglycerol (PG), one unidentified aminophospholipids (APL), two unidentified phospholipids (PL) and one unidentified lipid (L) and Q-10 as predominant respiratory quinone. The G + C content of the genomic DNA is 54.6 mol%.
The type strain, AK21\textsuperscript{T} (= MTCC 11704\textsuperscript{T} = JCM 18428\textsuperscript{T}) was isolated from a coastal sea surface water sample collected from sea shore, Rushikonda beach, Bay Bengal, Visakhapatnam, India.

Acknowledgements

We thank Council of Scientific and Industrial Research (CSIR), Directors of IMTECH, Chandigarh and NIO, Goa and Department of Biotechnology, Government of India for financial assistance. We would like to thank Mr. Deepak for his excellent help in sequencing DNA. TNRS is thankful to project PSC0105 for providing facilities and funding respectively. IMTECH communication number is XXX/2013 and NIO contribution number is xxxxx.

Table 2. Fatty acid composition of the strain AK21<sup>T</sup>, *M. mobilis* JCM 15154<sup>T</sup>, *M. xestospongiae* JCM 17469<sup>T</sup> and *M. hydrocarbonoclasticus* DSM 8798<sup>T</sup>

Results are presented as a percentage of the total fatty acids. Fatty acids amounting to 5% or more of the total fatty acids are in bold. Data were from present study. ND, not detected. The strains were grown on MA plates at 30°C for two to three days. ND, not detected. Values of less than 1% for all strains are not shown. tr, traces (<1%).

</table>

Summed features are groups of two or three fatty acids that could not be separated by GC with the MIDI system. Summed feature 3 comprised C₁₆:1 ω7c and/or iso-C₁₅:0 2-OH.
